Subject: Summary of RED primitives and their definitions as lambda notations.

Reference: RJ-1010

To: File

The attached sheets summarize the primitives for the RED system (pp. 61-64 of RJ-1010). Each primitive is accompanied by its definition as a LISP lambda expression.

P. D. Summers.

PDS/cah

965 - IBM - 04

Primitive Operators RED/1

Used through out the definitions in the following summary is the function npairp[x] which is a predicate defined to be false iff its argument, x, is a list containing exactly two items.

ie.

npairp[x] = not[equal[3; length [x]]]

(For definition of internal notation for RED expressions see the memo "Adding primitives to the RED System".)

The variable REDQUAD is global and evaluates to the RED $\square$ represented in this system by ? . All other functions are standard LISP functions.
